#### Abstract

In this paper the major findings of a formal experiment about onscreen text line lengths are presented. The experiment examined the effects of four different line lengths on the reading speed and the reading efficiency. Efficiency is defined as a combination of reading speed and accuracy. Sixteen people between the age of 24 and 36 participated at the experiment. The subjects had to read four different texts with an average line length around 2000 characters. The texts contained substitution words, which had to be detected by the subjects to measure reading accuracy. Besides objective measures like reading speed and accuracy, the subjects were asked to subjectively vote on their reading experience. The results from our objective measures show strong similarities to those of the work done previously by different researchers. The absolute reading speed grows when the line length grows from CPL (Characters Per Line) 30-120. The measured reading efficiency, however, doesn't grow steadily, although a growing trend can be seen. This is due to the fact, that the test persons found in average more substitution words from the 60 CPL text than they did from the 30 and 90 CPL texts. The reading speed seems to increase while the line length increases but the overall comprehension seems to peak at medium line lengths. As in the previous studies, our test persons also prefer the medium ( $\mathbf{6 0}$ and 90 CPL ) line lengths, although they perform better when reading longer lines. In the overall subjective opinion 13 out of 16 test persons selected the $\mathbf{6 0}$ or $\mathbf{9 0}$ CPL line length as their favorite. The literature doesn't truly provide a scientific explanation for the difference between the objective performance and the subjective preference. A natural hypothesis would be that the line length that is the fastest to read would also feel most comfortable to the readers but in the light of this and the earlier research it seems like this is not the case.

Key Words: Line Length, Reading Efficiency, Usability Testing.

## 1. INTRODUCTION

Researchers have been interested in finding the optimal line length since end of the 19th century. The research was concentrated on book and newspaper readability until in the 1980's the focus began to shift towards on-screen readability due to growing demand. The optimal line length is certainly different for newspapers, books and online information. Newspapers are most often using narrow line lengths. More wide lines are used in books and the on-screen line lengths vary a lot
due to different sized monitors. The first of the studies by Weber, [1]. Weber, A., came into a conclusion that the optimal line length for newspapers and books is four inches and in no case should it exceed six inches. Just about 50 years later,Tinker, et. al. [2] claimed that the optimal line length was between 3 and 3.5 inches. They also suggested that if line length is longer than 7.3 inches, the reader might not find the next line after finishing the previous one.

*** Assistant Professor, Department of Electronic Engineering, Mehran University of Engineering \& Technology, Jamshoro

The first ones to investigate the impact of line length to on-screen readability were Ducknicky, et. al. [3] whose results showed that text scaled to full screen width was significantly faster to read than text that filled only a third of the screen width [3]. In a study by Dyson, et. al. [4] suggested that the reading rate increases, with increasing number of letters per line. The study used a 12 point font. The slowest reading speed was noticed when line length was 4 inches, the fastest at 7.3 inches. But their testreaders preferred line lengths of 4 inches. Bernard, M., et. al., tested three different line lengths (3.3, 5.7 and 9.6 inches) with a 12 point sized font on a prose-text in [5]. Their results show no reliable differences in average reading speed between these three lengths. Shaikh, [6] also conducted the line length effect study for reading online news. Recently Holzinger, et. al. [7] has carried out a study for paper vs. screen with medical practitioners concluding that paper still has importance in people's lives.

In short one could say that, concerning the factual results, there is a tendency that a longer line length correlates with faster reading speed and that a medium line length correlates with a better overall comprehension. In most studies, however, the differences that were found are often non-significant. There is an agreement that lines shorter than 2.6 inches are not reasonable. Subjectively the users tend to prefer a medium line length (about 60 CPL ), Aschbacher, et. al. [8]. The aim of this study was to further investigate the effect of line length to on-screen readability.

## 2. TEST METHODOLOGY

### 2.1 User Profiles

Because the study discussed on-screen readability and particularly reading from the browser window the targeted potential user group is all Internet users. For practical reasons the subjects' age was limited between 18 and 40 years. The subjects were also expected to have some experience in computer use, to have normal or corrected-to-normal vision and to be native German speakers, as shown in Table 1.

Sixteen subjects volunteered for this study (13 Men and 3 Women). They ranged in age from 24-36 (Median 27.5) years. The average computer usage experience was 16.0 years (Median 15). The average computer work per week was 51.43 (Median 50). Most of the participants were employees or students; so they have lot of experience of on-screen reading. Most of them were working with MS

Windows and Firefox and most of them had already participated in other usability tests. Most of them preferred to magnify the text for reading online. The majority read newspapers online.

### 2.2 Test Design

The study used $4 \times 4$ factorial designs with line length and text as independent variables. The experiment was balanced through all of the 16 test users with a fully balanced Latin square design.

To determine the suitable line lengths for the study different commonly used web news pages were examined. Based on this examination following line lengths were selected: 30, 60, 90, and 120 CPL. The four texts were selected from www.derStandard.at (An Austrian Newspaper). Each of the texts has a length of approximately 2000 characters, as shown in Table 2.

In each text 10 words are replaced with other similar words. These substitution words are used to measure reading accuracy. The subjects had to find these words while reading the text samples. An example of a substitution word is rest->test, where a word is substituted with another, similar-sounding word, which doesn't make any sense in the context. Measured values were reading time, reading speed and reading efficiency. The efficiency is calculated as:

Efficiency $=($ Reading Speed $) *(\%$ Found Substitution Words $)$
Reading speed is measured in words per minute. Four different line lengths and text samples result in a $4 \times 4$ matrix with a total number of 16 different test cases. These test cases are arranged in a balanced Latin square as shown in Table 3.

### 2.3 Test Tasks

In this section we describe the test process. Each subject was assigned to a random test case, by picking a number from a bag. After that they had to fulfill an example test case, which introduced the test scenario. If the subject had no more questions about the test process, she/he was asked to pick the assigned test case from a dropdown menu. The first text was displayed and the subject had to read the text and speak out loud the substitution words. As the subject finished reading she/he had to push the "Fertig (Finish)" button. After that she/he could continue to the next text, by pushing the "Start" button. The time
between the start of a text and the end was measured by the server side protocol of the test environment. On the software side the test environment was set up with the help of a XAMPP Server. The texts were displayed as HTML with the use of the Firefox Web browser maximized to the computer's native resolution. The texts were rendered with the font Verdana in size 12 point. The text color was black (\#000000) on a slightly gray background (\#F0F0F0). The dedicated line lengths were created by tables with fixed widths and the Firefox native line break. The texts and all other necessary data was stored in a database by the PHP server, which stored the measured timing either. The texts were taken from the online news portal derStandard.at. All 4 texts are tourist reports from different locations. They are all around 2000 characters. The reference from the Latin square distribution is mentioned in the brackets. The introduction text was presented to each subject before the test.

### 2.4 Test Environment

The tests were recorded with a digital video camera and an external microphone. The test utility software was installed on an Acer Aspire 1710 Laptop, which has an Intel P4 (3.4 GHz) processor, 1 GB RAM, a 17" LCD-display with resolution of $1280 \times 1024$ and 16.7 million colors. The
operating system was Windows XP Professional SP2. During the actual tests there were three facilitators in the room in addition to the actual test person: one was operating the camera, one the microphone and one was running the tests with the test person.

## 3. RESULTS

The measurement was divided into two parts. The first part is the objective measurement, which is a combination of the reading speed and the correct substitution words found. The second part is the subjective measurement, which reflects the subjects own experience. The objective measurement performed with a steady increase in reading speed and also an increase in efficiency. The correct found substitution words had an average around 6.5 out of 10 for all 4 line lengths.

TABLE 2. TEXTS CONTAINING CHARACTERS AND WORDS

| Taxt No. | Characters | Words |
| :---: | :---: | :---: |
| 1 | 2070 | 280 |
| 2 | 1985 | 290 |
| 3 | 1950 | 204 |
| 4 | 1997 | 264 |

TABLE 1. PARTICIPANTS' DESCRIPTION

| No. | Gender | Age | Profession | Vision | Color Blind | Education | PC <br> Exp <br> (Years) | PC <br> Work/ <br> Week |  | OS |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

The subjective measures showed, that most people liked a line length between 60 and 90 because $43.7 \%$ preferred the 60 CPL and $37.5 \%$ liked the 90 CPL the most, which is more than $80 \%$ of the test subjects. These figures correlate with the subjective answers from reading speed, reading accuracy and readability.

### 3.1 Objective Measures

In this section we will analyze our measurements of reading speed and substitution words found. The Tables 4-7 represent the 4 different states of the measured variable of interest. For each value, we gathered the time it took a subject to read the text and the substitution words found. The timing was automatically done by the computer. The substitution words were written down, by the moderator of the test. False recognized substitution words were not taken into account, as they are not interested for our study. (The substitution words are present to ensure a valuable reading; in addition to that false recognized words are still an indicator for valuable reading). The gathered values were statistically analyzed. The most important calculation in the Tables $4-7$ is efficiency. This value is the overall time it took a subject to read the text according to the length of

| 15 | 120 | 90 | 30 | 60 |
| 16 | 90 | 60 | 120 | 30 |

the text and the substitution words found. With this value, we can say, how fast and accurate a subject read the text. Moreover, all other variable values, like text length or substitution words are equally distributed. An analysis over the actual found values is described after the tables. Formula for the efficiency algorithm is given by:
Efficiency $=\frac{\text { Found Substitution Words } *\left(\frac{\text { Words }}{\text { Time }}\right)}{}$

## Total Substitution Words

Overall it can be said, that the reading speed is going up for longer line lengths, but not steadily. The difference of around fifteen seconds from 60 CPL (Table 5) to 120 CPL (Table 7) is quite remarkable as this is a boost of around $9 \%$. Moreover we found out, that the accuracy in found substitution words has its peak at the longest line either (Table 7).

After taking into account the overall length of the text and the absolute reading speed, the efficiency showed a steady rising from 30-120 CPL. So the expansion of the line length from 30-120 CPL brought an increase in efficiency of approximately $13 \%$ (Tables 4 and 7). The standard deviation of the efficiency has a minimum in the 120 CPL test with 17.94 (Table 7) and a maximum at 60 CPL with 29.54 (Table 5 ), which is nearly $40 \%$ of the mean value.

### 3.2 Subjective Measures

Following feedback survey Tables 8-11 show readability, reading speed, reading accuracy and preferred line length.

The results from the feedback questionnaires show that our test participants preferred 60 CPL (7 out of 16 participants), followed by 90 CPL ( 6 out of 16 participants). The worst preferred text was 30 CPL (1 out of 16 participants); Table 11. For the good readability of texts, 60 CPL text was rated with an average of 3.94 (Table 8), followed by 90 CPL (an average of 3.50). The 120 CPL text had the worst readability rating (an average of 2.81). Again 60 CPL text was rated with an average of 3.81 as having good reading speed, followed by 90 CPL (an average of 3.38); Table 9. The 120 CPL text again had the worst reading speed rating (an average of 2.81). But 90 CPL text was rated with an average of 3.75 as having good reading accuracy, followed by 60 CPL (an average of 3.38). 30 CPL text had the worst reading accuracy (an average of 2.25), see Table 10.

## 4. CONCLUSIONS

The results from our objective measures show strong similarities to those of the work done previously by different researchers. The absolute reading speed grows when the line length grows from 30-120 CPL. The measured reading efficiency, however, doesn't grow steadily, although a growing trend can be seen. This is due to the fact, that the test persons found in average more substitution words from the 60 CPL text than they did from the 30 and 90 CPL texts. This indicates a similar conclusion: The reading speed seems to increase while the line length increases but the overall comprehension seems to peak at medium line lengths. As in the previous studies, our test persons also prefer the medium ( 60 and 90 CPL) line lengths, although they perform better when reading longer lines. In the overall subjective opinion 13 out of 16 test persons selected the 60 or 90 CPL line length as their favorite. The literature doesn't truly provide a scientific explanation for the difference between the objective performance and the subjective preference. A natural hypothesis would be that the line length that is the fastest to read would also feel most comfortable to the readers but in the light of this and the earlier research it seems like this is not the case. As a difference is found between the objective and subjective results, the final decision has to be made by the web designers: do they give more value to the actual reading speed or the subjective preference of the readers. The difference in reading efficiency between 60 or 90 CPL texts and the 120 CPL text was not drastic but only 2 test persons out of 16 selected the 120 CPL line length as their preference. Because the web is among other things a highly visual media it could be suggested that the benefits gained with the longer line length are less important than the losses it causes in overall user preference. Although the differences found in our study are not obvious, one could suggest based on our results that for general web use the medium line lengths (close to $60-90 \mathrm{CPL}$ ) are a safe compromise between subjective user preference and overall reading efficiency.

Future work will concentrate on conducting the same type of study in the context of Pakistani users for reading newspapers like Dawn, etc. as well as reading on the tiny screens of hand-held mobile devices and tablets.

## ACKNOWLEDGEMENTS

The authors are highly thankful to Higher Education Commission of Pakistan, Technical University of Graz, Austria, Vienna University of Technology, Austria, Quaid-e-Awam University of Engineering, Science \& Technology, Nawabshah, and Mehran University of Engineering \& Technology, Jamshoro, Pakistan, for providing necessary funding and research facilities during their research studies.
